

CONSTITUTION.md â€” Doc-Processor

INHERITED FROM the Helix Constitution

This module is governed by the Helix Constitution. All rules in the constitutionâ€™s `Constitution.md` and the `Constitution.md` it references apply unconditionally. Locate the constitution from any nested depth via its `find_constitution.sh` helper â€” do NOT hardcode a path (this module stays fully decoupled and project-agnostic per Â§11.4.28).

Canonical reference: <https://github.com/HelixDevelopment/HelixConstitution>

Mission

DocProcessor turns project documentation into structured, queryable feature maps and verification-coverage data for QA automation, while remaining a standalone, project-not-aware, fully decoupled Go module (`digital.vasic.docprocessor`).

Module-Specific Mandatory Standards

This module extends the Helix Constitution; it adds no overrides that relax any canonical rule. The following are concrete, code-enforced restatements scoped to this module:

- Decoupling: no code under `pkg/**` or `cmd/**` may import a consuming projectâ€™s namespace. Project-specific behaviour is injected only via the `Translator`, `LLMAgent`, and `Config` contracts.
- No hardcoded user-facing content: every CLI line is emitted through the injected `i18n.Translator`; message IDs live in `pkg/i18n/bundles/active.en.yaml`. `NoopTranslator` is a loud fallback that returns the message ID verbatim.
- Secrets hygiene: `.env` is git-ignored and must be `chmod 600`; only `.env.example` (placeholder values) is committed.
- Quality gates: `go build ./...` and `go vet ./...` must pass with zero warnings, and the full suite (`go test ./... -race`) â€” unit, integration, stress, security, E2E, automation â€” must pass against real infrastructure (filesystem and the real CLI binary), never via stubbed or skipped tests.
